

SOLID Principles in Software Development

1. Single Responsibility Principle (SRP)

A class should have only one reason to change, meaning it should have only one job or responsibility.

Violating SRP: This class handles both employee data and saving it to the database.

```
class Employee:
```

```
    def __init__(self, name, salary):
```

```
        self.name = name
```

```
        self.salary = salary
```

```
    def save_to_database(self):
```

```
        pass # Code to save employee data to the database
```

Following SRP: Separate the employee data from database handling

```
class Employee:
```

```
    def __init__(self, name, salary):
```

```
        self.name = name
```

```
        self.salary = salary
```

```
class EmployeeDatabase:
```

```
    def save(self, employee):
```

```
        pass # Code to save employee to database
```

2. Open/Closed Principle (OCP)

Software entities (classes, functions, etc.) should be open for extension but closed for modification.

Violating OCP: Modifying the shape area calculation every time a new shape is added

```
class Shape:
```

```
    def area(self):
```

```
        pass
```

```
class Rectangle(Shape):
```

```
    def __init__(self, width, height):
```

```
        self.width = width
```

```
        self.height = height
```

```
    def area(self):
```

```
        return self.width * self.height
```

```
class Circle(Shape):
```

```
    def __init__(self, radius):
```

```
        self.radius = radius
```

```
    def area(self):
```

```
        return 3.14 * self.radius * self.radius
```

Following OCP: Adding a new shape without modifying existing code

```
class ShapeCalculator:
```

```
    def calculate_area(self, shape):
```

```
return shape.area()
```

3. Liskov Substitution Principle (LSP)

Objects of a superclass should be replaceable with objects of a subclass without altering the correctness of the program.

Violating LSP: A Square class that overrides the behavior of Rectangle in an unexpected way

```
class Rectangle:
```

```
    def __init__(self, width, height):
```

```
        self.width = width
```

```
        self.height = height
```

```
    def area(self):
```

```
        return self.width * self.height
```

```
class Square(Rectangle):
```

```
    def __init__(self, side):
```

```
        super().__init__(side, side) # This may violate LSP as a square is a specific type of rectangle
```

Following LSP: Defining Square and Rectangle separately

```
class Shape:
```

```
    def area(self):
```

```
        pass
```

```
class Rectangle(Shape):
```

```
    def __init__(self, width, height):
```

```
self.width = width
```

```
self.height = height
```

```
def area(self):
```

```
    return self.width * self.height
```

```
class Square(Shape):
```

```
    def __init__(self, side):
```

```
        self.side = side
```

```
    def area(self):
```

```
        return self.side * self.side
```

4. Interface Segregation Principle (ISP)

A client should not be forced to implement interfaces it does not use.

Violating ISP: A large interface that forces implementation of unrelated methods

```
class Machine:
```

```
    def print(self):
```

```
        pass
```

```
    def scan(self):
```

```
        pass
```

```
    def fax(self):
```

```
        pass
```

Following ISP: Splitting interfaces into smaller, more specific interfaces

```
class Printer:
```

```
    def print(self):
```

```
        pass
```

```
class Scanner:
```

```
    def scan(self):
```

```
        pass
```

```
class Fax:
```

```
    def fax(self):
```

```
        pass
```

```
class MultiFunctionPrinter(Printer, Scanner, Fax):
```

```
    pass # Implements all functionalities as needed
```

5. Dependency Inversion Principle (DIP)

High-level modules should not depend on low-level modules; both should depend on abstractions.

Additionally, abstractions should not depend on details; details should depend on abstractions.

Violating DIP: High-level class depends on low-level class directly

```
class LightBulb:
```

```
    def turn_on(self):
```

```
        pass
```

```
def turn_off(self):
```

```
    pass
```

```
class Switch:
```

```
    def __init__(self, bulb: LightBulb):
```

```
        self.bulb = bulb
```

```
    def operate(self, on: bool):
```

```
        if on:
```

```
            self.bulb.turn_on()
```

```
        else:
```

```
            self.bulb.turn_off()
```

Following DIP: High-level class depends on an abstraction

```
class Switchable:
```

```
    def turn_on(self):
```

```
        pass
```

```
    def turn_off(self):
```

```
        pass
```

```
class LightBulb(Switchable):
```

```
    def turn_on(self):
```

```
        pass
```

```
    def turn_off(self):
```

pass

class Switch:

def __init__(self, device: Switchable):

self.device = device

def operate(self, on: bool):

if on:

self.device.turn_on()

else:

self.device.turn_off()
